The key challenge of embedded system design

• Supporting overall design flow

• Addressing heterogeneity in:
  - System
  - Skills/teams/tools/methods

• Supporting complex OEM/supplier chains

PLM
This leaf is a valve it has a Catia model a Simulink physical model and a SCADE software
This subsystem has a Rhapsody model and a reliability model. It is deployed on a set of LRU's communicating over an ARINC 643 bus.
Aim of this course is to substantiate why the Polychronous paradigm is a good solution for system level co-modeling.
I am kindly asking you for a while to forget everything you know about embedded software...

- RTOS, RME, tasking, scheduling
- Bus, networking
- Components, reuse, COTS
- Architectures, dependability
- Simulink, ladder diagrams
- Whataveyou...
... and to remember instead some basic maths you learnt while being undergraduate ...

- Specifying sets or surfaces via equations
- Intersecting them by means of systems of equations
- Systems of equations do combine easily: they are just systems of systems of equations = systems of equations
- Systems of equations possess 0 / 1 / many solutions
- Equations can be dynamical (differential equations, difference equations)
- Solving equations may be difficult
... and to compare it with your actual engineering knowledge

- Specifying sets or surfaces via equations
- You want to (re)use components

- Systems of equations combine easily: they are just systems of systems of equations = systems of equations
- Systems of equations possess no / one / many solutions
- Equations can be dynamical (differential equations, difference equations)
- Solving equations may be difficult
- You want to (re)use components
- Designing systems by assembling components
- Computer scientists have developed huge bodies of theory about how to compose things; standardisation bodies have debated this even more
- Composition may be blocking or may not be executable due to nondeterminism; otherwise we are happy
- Embedded systems involve reactive and real-time components
- Get executable code for the component and run it
... and to compare it with your actual engineering knowledge

easy: composing
difficult: executing

composing: difficult
executing: « easy »
Guess which is the best paradigm for component based system design?
Signal/Polychrony has chosen to rely on the math paradigm

- This has made much more easy all issues related to composition of components
- Some more traditional issues like compilation and code generation become (very) difficult - the theory for it amounts to solving equations in particular domains
Contents

- Motivation
- Signal Model of Computation and Communication
- Key data structure for Signal compilation: clock-and-causality calculus
- Constructive Semantics
- Separate compilation and a notion of interface
- Deploying over distributed (possibly asynchronous) architectures
- Use in architecture modeling and analysis
The Essence of Polychrony (1)

- Synchronous hardware
- Ed Lee’s Synchronous dataflow
- Simple Simulink diagrams

- Each module has a single clock that triggers all signals
- The different clocks are derived from a global master clock via a frequency/phase mechanism
- Systems of difference equations in maths
The Essence of Polychrony (2)

- Synchronous software:
  - “if-then-else” statements activate their children statements
  - Each module has a single clock that triggers all signals
  - The different clocks are derived from a global master clock via a boolean clock mechanism, recursively
Open systems with synchronous software components:

- Prepared to accept more components
- Each module is synchronous software
- There is no global master clock
- The different clocks can be related by synchronization constraints
The Essence of Polychrony (4)

- **Open systems** with synchronous software components:
  Polychronous

- If no synchronization constraints: asynchronous!!
The Essence of Polychrony (5)

- **Open systems** with synchronous software components: Polychronous

- The different clocks can be related by synchronization constraints

![Diagram of synchronization and monitoring systems]
Pushing Polychrony to its limits: Signal

- **Open systems** with synchronous software components:
  - Prepared to accept more components
  - Each module is synchronous software
  - There is no global master clock
  - The different clocks can be related by synchronization constraints

- Each individual signal has its own private clock
- There is no global master clock
- The different clocks can be related by synchronization constraints
Pushing Polychrony to its limits: Signal

- Clocks act as a typing system
- Clock synchronization is difficult by hand
- Hence clock synchronization is synthesized, not verified

This is unlike Lustre, where clocks are only verified

⇒ replaced in practice by activation conditions, which do not act as types

These design choices are debatable

- Each individual signal has its own private clock
- There is no global master clock
- The different clocks can be related by synchronization constraints
Below is a pseudo code that we shall discuss

```
loop
    [ when X>0 then
        [get Y ; emit Z=Y+pre(Y)] ]

    [ present X then
        [ present Z then emit U=X+Z
          else emit V=2X ] ]
end
```

Contents

• Motivation

• Signal Model of Computation and Communication

• Key data structure for Signal compilation: clock-and-causality calculus

• Constructive Semantics

• Separate compilation and a notion of interface

• Deploying over distributed (possibly asynchronous) architectures

• Use in architecture modeling and analysis
What is the problem?

• As we have seen, Signal programs are systems of equations with dynamics

• This makes parallel composition straightforward defining and studying: associative and commutative (allows for flexible re-architecturing)

• However, there is no free lunch: systems of equations are declarative, not operational. Producing executable code in fact amounts to “solving” these systems of equations for their outputs, regarding inputs as free parameters. Think of

\[ AX = B \Rightarrow X = f(A,B) \]

• Computable solutions do not generally exist for the kind of equations we get with Signal (data types are not restricted). We thus need a specific abstraction mechanism for solving these equations. We study it now in details.
The old fashioned Signal watch

This is an old mechanical watch like the one I have. Turn the spring. The watch goes for some time, and then stops. When it stops, turn again the spring... and so on...

This is an interesting example, as the output up-samples the input. We show how to analyze and execute it.
The old fashioned Signal watch

\[
(\ X := \text{IN default } ZX - 1 \\
| \ ZX := X$1 \text{ init } 0 \\
| \text{IN } ^\wedge = \text{when } (ZX \leq 0) \\
) \\
\]

Signal program
Input IN
Returns X
The old fashioned Signal watch

(  X := IN default ZX-1
|  ZX := X$1 init 0
|  B := (ZX < 0)
|  IN ^= when B
|  H ^= B ^= X ^= ZX
)

Signal program, expanded to facilitate manual analysis
The old fashioned Signal watch

\[
\begin{align*}
(X :&= \text{IN default } ZX-1 \\
ZX :&= X$1 \text{ init } 0 \\
B :&= (ZX \leq 0) \\
\text{IN }^= &\text{ when } B = [B] \\
H &\text{ }^= B \text{ }^= X \text{ }^= ZX
\end{align*}
\]

We show how to represent in a unique data structure both the synchronisation and the dependencies.

Then we show how this data structure can be used to generate schedulings for execution.
Intermezzo: back to solving equations

- Solving equations: which abstraction?
  \[ X := A+B \]

- We interpret operator + in an abstract way, by rewriting: substitute X for the expression A+B everywhere X occurs in the program

- Rewriting is best encoded using Directed Graphs
  \[(A,B) \rightarrow X\]

- However, such causality constraints are generally state dependent. We capture this by labeling them with clocks.
The old fashioned Signal watch: scheduling and executing

\begin{align*}
&\begin{aligned}
&X := IN \text{ default } ZX-1 \\
&ZX := X^1 \text{ init } 0 \\
&B := (ZX < 0) \\
&IN := \text{ when } B = [B] \\
&H := B \land X \land ZX \\
&\end{aligned}
\end{align*}
The old fashioned Signal watch: scheduling and executing

\[
\begin{align*}
X &:= \text{IN default } ZX-1 \\
ZX &:= X \& l \text{ init } 0 \\
B &:= (ZX \leq 0) \\
\text{IN} &:= \text{when } B = [B] \\
H &:= B \triangleright X \triangleright ZX
\end{align*}
\]
The old fashioned Signal watch: scheduling and executing

(X := IN default ZX-1
| ZX := X$1 init 0
| B := (ZX < 0)
| IN ^= when B = [B]
| H ^= B ^= X ^= ZX
)

\end{align*}
\]
Clock & Causality Analysis: the key data structure

\[
( \begin{align*}
  B & := (ZX \leq 0) \\
  IN & ^= \text{when } B = [B] \\
  H & ^= B ^= X ^= ZX \\
  X & \leftarrow IN \text{ when } B \\
  X & \leftarrow ZX \text{ when not } B \\
  B & \leftarrow (H,ZX) \\
  [B] & \leftarrow B \\
  ZX & \leftarrow H \\
  IN & \leftarrow [B] \\
\end{align*} )
\]

Part of Signal syntax
Clock & Causality Analysis: the key data structure

\[
\begin{align*}
\text{(} & \hspace{1cm} \text{( B := (ZX \leq 0) } \\
& \text{ | IN := when } B = [B] \\
& \text{ | H := B := X := ZX )} \\
& \text{ | X := IN when } B \\
& \text{ | X := ZX when not } B \\
& \text{ | B := (H,ZX) } \\
& \text{ | [B] := B } \\
& \text{ | ZX := H } \\
& \text{ | IN := [B] )}
\end{align*}
\]

Part of Signal syntax

- {scheduling + synchronization}
- a calculus of the Signal engine
- an interface model
  - right support for separate compilation
  - islands of fully rigid scheduling can be safely compiled to C
Think again of equations in high school linear algebra, where \((a,b)\) are constants:

\[
\begin{align*}
ax+uy &= 0 \\
bx+vy &= 0
\end{align*}
\]

Solving for \((x,y)\) amounts to declaring \((u,v)\) as inputs and \((x,y)\) as outputs.

However, we learnt that, depending on the values of constants \((a,b)\), map \((u,v) \rightarrow (x,y)\) may possess:

- 1 solution “well defined, deterministic, executable”
- 0 solution “blocking, no semantics”
- \(\infty\) solution “nondeterministic, no semantics”

A signal may have a schizophrenic status: partially/sometimes input/output.
Think again of equations in highschool linear algebra, where \((a,b)\) are constants:

\[
\begin{align*}
ax + uy &= 0 \\
bx + vy &= 0
\end{align*}
\]

Solving for \((x,y)\) amounts to declaring \((u,v)\) as inputs and \((x,y)\) as outputs.

However, we learnt that, depending on the values of parameters \((a,b)\), map \((u,v) \mapsto (x,y)\) may possess:

- 1 solution \(\Rightarrow \) "well defined, deterministic, executable"
- 0 solution \(\Rightarrow \) "blocking, no semantics"
- \(\infty\) solution \(\Rightarrow \) "nondeterministic, no semantics"

A signal may have a schizophrenic status: partially/sometimes input/output

Intermezzo: inputs and outputs are not just a syntactic, but a semantic notion.

```plaintext
( ( B := (ZX \leq 0)
  | IN ^= when B = [B] output: clock(IN)
  | H ^= B ^= X ^= ZX ) input: clock(X)
  | X \leftarrow IN when B input: val(IN)
  | X \leftarrow ZX when not B output: val(X)
  | B \leftarrow (H,ZX)
  | [B] \leftarrow B
  | ZX \leftarrow H
  | IN \leftarrow [B] )
)
```

- A signal may have a schizophrenic status: partially/sometimes input/output
The very-old fashioned Signal watch

This is an even older watch! The difference with the previous one is the following: when the watch goes, then the weights move “backward”, back to their initial position.

Thus, for this watch, the weights play alternatively the role of an input (when the user moves the weights), and of an output (when the watch goes).

This causes a cycle in dependencies.
The very-old fashioned Signal watch

\[
\begin{align*}
| & X := (IN \text{ when } B) \text{ default } ZX-1 \\
| & ZX := X$1 \text{ init } 0 \\
| & B := (ZX \leq 0) \\
| & H := B \quad X := ZX \quad IN \\
| & IN := X \quad \text{when not } B \\
| & )
\end{align*}
\]

The backward move of the weights is captured by the yellow statement, where IN becomes an output!
The very-old fashioned Signal watch

| X := (IN when B) default ZX-1 |
| ZX := X$1 init 0 |
| B := (ZX ≤ 0) |
| [B] := when B |
| H := B ^= X ^= IN |
| IN := X when not B |
| ) |

State inclusion & causality

Case 1
The very-old fashioned Signal watch

\[
\begin{align*}
| & \quad X := (IN \text{ when } B) \text{ default } ZX - 1 \\
| & \quad ZX := X$1 \text{ init } 0 \\
| & \quad B := (ZX \leq 0) \\
| & \quad [B] := \text{ when } B \\
| & \quad H \Leftarrow B \Leftarrow X \Leftarrow IN \\
| & \quad IN := X \text{ when not } B \\
| &)
\end{align*}
\]

State inclusion & causality

Case 1
The very-old fashioned Signal watch

\[
\begin{align*}
| X &:= (IN \text{ when } B) \text{ default } ZX - 1 \\
| ZX &:= X$1 \text{ init } 0 \\
| B &:= (ZX \leq 0) \\
| [B] &:= \text{ when } B \\
| H &:= B \wedge X \wedge IN \\
| IN &:= X \text{ when not } B \\
|
\end{align*}
\]

State inclusion & causality

Case 1
The very-old fashioned Signal watch

(| X := (IN when B) default ZX-1
| ZX := X$1 init 0
| B := (ZX ≤ 0)
|[B] := when B
| H ^= B ^= X ^= IN
| IN := X when not B
|)

State inclusion & causality

Case 1
Summary: the clock-and-causality calculus, an interface model

Clock-and-causality abstraction
- encodes all valid schedules for each state of the program
- obeys the graph algebra below
- sufficient interface model for single designer component based design
- not enough for distributed multi-team development (contracts needed)

\[
\begin{align*}
B & := (ZX \leq 0) \\
IN & := \text{when } B = \lfloor B \rfloor \\
H & := B \Rightarrow X \Rightarrow ZX \\
X & \leftarrow \text{IN when } B \\
X & \leftarrow ZX \text{ when not } B \\
B & \leftarrow (H,ZX) \\
\lfloor B \rfloor & \leftarrow B \\
ZX & \leftarrow H \\
\text{IN} & \leftarrow \lfloor B \rfloor
\end{align*}
\]

\[
\begin{align*}
X & \Leftarrow Y \text{ when } B \\
X & \Leftarrow Y \text{ when } C
\end{align*}
\Rightarrow
\begin{align*}
X & \Leftarrow Y \text{ when } B \text{ default when } C
\end{align*}
\]

\[
\begin{align*}
X & \Leftarrow Y \text{ when } B \\
Y & \Leftarrow Z \text{ when } C
\end{align*}
\Rightarrow
\begin{align*}
X & \Leftarrow Z \text{ when } B \text{ when } C
\end{align*}
\]
Summary: the clock-and-causality calculus, a framework for compilation

Clock-and-causality abstraction
- encodes all valid schedules for each state of the program
- intermediate code for separate compilation:
  * sequentialize when no room left for concurrency
  * otherwise keep concurrent
- compilation by Signal → Signal program rewriting

```
( ( B := (ZX ≤ 0) |
  | IN ^= when B = [B] |
  | H ^= B ^= X ^= ZX ) |
  |
  ( X ← IN when B |
  | X ← ZX when not B |
  | B ← (H,ZX) |
  | [B] ← B |
  | ZX ← H |
  | IN ← [B] )
```
Assume causal correctness: \(H_1 \cap H_2 \cap H_3 = \emptyset\). If \(H_i \cap H_j \neq \emptyset\) then three different cuts are required \(\Rightarrow\) three replicas are necessary.
If $H_1 \cap H_2 = \emptyset$, $H_2 \supseteq H_3$, then two different cuts are required, thus two replicas only are necessary.

The essence of constructive semantics

Lustre

• A Lustre program with no zero-delay loop is a *stream function* in Kahn sense
• Execution follows as a Kahn Process Network
• Executions can (but need not) be synchronized as a sequence of global reactions
• Simple, no need for any kind of Constructive Semantics
# The essence of constructive semantics

## Lustre

- A Lustre program with no zero-delay loop is a *function* in Kahn sense
- Execution follows as a Kahn Process Network
- Executions can (but need not) be synchronized as a sequence of global reactions
- Simple, no need for any kind of Constructive Semantics

## Signal

- Due to the possibility of constraints relating clocks, Signal programs can be deterministic, nondeterministic, or "schizophrenic"
- Difficulties:
  - Non-determinism
  - Causality analysis
- Need special work to
  - Check if a program is deterministic
  - Schedule evaluation actions (micro-steps)
- Constructive Semantics takes care of this
The essence of constructive semantics

**Esterel**

- Due to the possibility of *instantaneous dialogs*, Esterel programs can be deterministic, nondeterministic, or “schizophrenic”

- Difficulties:
  - Non-determinism
  - Causality analysis

- Need special work to
  - Check if a program is deterministic
  - Schedule evaluation actions (micro-steps)

- Constructive Semantics takes care of this

**Signal**

- Due to the possibility of *constraints relating clocks*, Signal programs can be deterministic, nondeterministic, or “schizophrenic”

- Difficulties:
  - Non-determinism
  - Causality analysis

- Need special work to
  - Check if a program is deterministic
  - Schedule evaluation actions (micro-steps)

- Constructive Semantics takes care of this
The essence of constructive semantics

Esterel

- Due to the possibility of instantaneous dialogs, Esterel programs can be deterministic, nondeterministic, or “schizophrenic”

- Difficulties:
  - Non-determinism
  - Causality analysis

- Need special work to
  - Check if a program is deterministic
  - Schedule evaluation actions (micro-steps)

- Constructive Semantics takes care of this

Example [Berry 97]

Logically incorrect

module P3:
output O;
present O else emit O end
end module

Nondeterministic:

module P4:
output O;
present O then emit O end
end module
The essence of constructive semantics

Example

Nondeterministic: a mailbox with asynchronous reads and writes

\[
X := \text{IN default (}X\$1) \\
| \text{OUT} := \ X \ \text{when event OUT}
\]

yields clock constraints

\[
X \ ^> \ \text{IN} \\
| \text{OUT} \ ^< \ X
\]

Signal

- Due to the possibility of constraints relating clocks, Signal programs can be deterministic, nondeterministic, or "schizophrenic".

- Difficulties:
  - Non-determinism
  - Causality analysis

- Need special work to
  - Check if a program is deterministic
  - Schedule evaluation actions (micro-steps)

- Constructive Semantics takes care of this
The essence of constructive semantics

Example

Nondeterministic: a mailbox with asynchronous reads and writes

\[ X := \text{IN default } (X$1) \]
\[ \mid \text{OUT := } f(X) \text{ when event OUT} \]

yields clock constraints

\[ X \rightarrow \text{IN} \]
\[ \mid \text{OUT } \leftarrow X \]

subtle causality analysis

Signal

- Due to the possibility of constraints relating clocks, Signal programs can be deterministic, nondeterministic, or "schizophrenic".
- Difficulties:
  - Non-determinism
  - Causality analysis
- Need special work to
  - Check if a program is deterministic
  - Schedule evaluation actions (micro-steps)
- Constructive Semantics takes care of this
The essence of constructive semantics

Example cont'd

Instantaneous dialog

\[ X := \text{IN default (X}$-1$) \]
\[ | \text{IN } \wedge = \text{when } X<0 \]

yields additional clock constraint

\[ X \wedge > \text{IN} \]

causality analysis should reveal a causality circuit

Signal

- Due to the possibility of constraints relating clocks, Signal programs can be deterministic, nondeterministic, or “schizophrenic”
- Difficulties:
  - Non-determinism
  - Causality analysis
- Need special work to
  - Check if a program is deterministic
  - Schedule evaluation actions (micro-steps)
- Constructive Semantics takes care of this
The essence of constructive semantics

### Esterel: summary

- Due to the possibility of **instantaneous dialogs**, Esterel programs can be deterministic, nondeterministic, or “schizophrenic”

- **Difficulties:**
  - Non-determinism
  - Causality analysis

- **Need special work to**
  - Check if a program is deterministic
  - Schedule evaluation actions (micro-steps)

- **Constructive Semantics takes care of this**

### Signal: summary

- Due to the possibility of **constraints relating clocks**, Signal programs can be deterministic, nondeterministic, or “schizophrenic”

- **Difficulties:**
  - Non-determinism
  - Causality analysis

- **Need special work to**
  - Check if a program is deterministic
  - Schedule evaluation actions (micro-steps)

- **Constructive Semantics takes care of this**
The role of constructive semantics

Program

- Each program fragment generates a causality constraint inducing a scheduling constraint

Scheduling constraints

- Combine them with the actual evaluation of variables
- Each variable is evaluated once
- Yields a description of all correct schedules for executing the program (if any)

Yields micro-step semantics for the program
The essence of constructive semantics

**Esterel**

- Scott domain for signals
  - $\perp$, present, absent
- Facts attached to control actions
  - Must
  - Cannot
- Causality relations
  - From control actions to the evaluation of signals and variables
  - From a context to the evaluation of Must and Cannot for a control action
- $\perp$: not yet evaluated

**Signal**

- Scott domain for clocks and signals
  - $\perp$, true, false, (any), absent
- Facts: values of
  - Clocks
  - Boolean Signals
- Causality relations
  - From a clock to the signal evaluation it triggers
  - From signals to clocks of the form when $B$, for $B$ a predicate involving these signals
  - Between signals in data-flow expressions
The essence of constructive semantics

Causality relations generate Scheduling Constraints

- Scott domain for signals
  - \( \bot \), present, absent
- Facts attached to control actions
  - Must
  - Cannot
- Causality relations
  - From control actions to the evaluation of signals and variables
  - From a context to the evaluation of Must and Cannot for a control action
- Scott domain for clocks and signals
  - \( \bot \), true, false, (any), absent
- Facts: values of
  - Clocks
  - Boolean Signals
- Causality relations
  - From a clock to the signal evaluation it triggers
  - From signals to clocks of the form \( \text{when } B \text{, for } B \text{ a predicate involving these signals} \)
  - Between signals in data-flow expressions
Constructive Semantics in Signal

Three equivalent representations:
- Clock and causality graph (already seen)
- Scott domain
- Micro-step automata

\[
\begin{align*}
\text{val} & := (\text{ZX} \leq 0) \\
\text{IN} & := \text{when } B = [B] \\
\text{H} & := B \wedge X \wedge ZX \\
\text{IN} & := [B] \\
\text{IN} & := \text{when } B \\
\text{ZX} & := \text{when not } B \\
\text{B} & := (H, ZX) \\
[B] & := B \\
\text{H} & := \text{when } B \\
\text{ZX} & := \text{when } [B] \\
\end{align*}
\]
Constructive Semantics in Signal

Three equivalent representations:
- Clock and causality graph
- Scott domain
- Micro-step automata
Scott domain

\( \bot: \) not yet evaluated  
\( *: \) absent

\[ D = \{ \bot, *, F, T \} \]

\( \bot < *, F, T \): Scott domain

\( F, T, \text{any} \) subsumed by \( \bot \)
Scott domain

\( \perp: \text{not yet evaluated} \)

\( \ast: \text{absent} \)

\[ D = \{ \perp, \ast, F, T \} \]

\( \perp < \ast, F, T \): Scott domain

\( F, T, \text{any} \) subsumed by \( \ast \)

This way, we can model both the value of a signal and its current status within the current reaction:

**not yet evaluated vs. evaluated**

Using this Scott domain, encode all SIGNAL statements (in doing this, abstraction is performed)
$X \rightarrow_{B} Y$

as a constraint in the Scott domain

\[ Y := f(X) \]
as a constraint in the Scott domain

\[(H \rightarrow X) | (X \rightarrow Y) \text{ where } H^=X^=Y\]
1. Each Signal reaction is fully abstracted as a system of equations in Scott domain; yields a set $\Sigma$ of configurations for all variables.
Results (1)

1. Each Signal reaction is fully abstracted as a system of equations in Scott domain; yields a set $\Sigma$ of configurations for all variables.

2. One step of sequential evaluation consists in changing the value of a single variable, from $\perp$ to $\not=\perp$, while staying within $\Sigma$.
1. Each Signal reaction is fully abstracted as a system of equations in Scott domain; yields a set $\Sigma$ of configurations for all variables.

2. One step of sequential evaluation consists in changing the value of a single variable, from $\bot$ to $\neq \bot$, while staying within $\Sigma$

3. Executing the reaction amounts to finding a connected path in $\Sigma$ that starts at $(\bot, \ldots, \bot)$ and ends at $(\neq \bot, \ldots, \neq \bot)$; call such a path an execution path (not unique in general)
Results (2): relating Scott semantics to clock & graph semantics

1. If the clock&causality graph is circuit free, then execution paths exist; each execution path corresponds to a valid sequential execution of the program.

2. This way of getting valid executions is compositional: systems of Scott equations can be composed.

⇒ supports separate compilation.
Constructive Semantics in Signal

Three equivalent representations:

- Clock and causality graph
- Scott domain
- Micro-step automata
as an accepting automaton

\[ X \rightarrow_B Y \]
$Y := f(X) \mid H \rightarrow X \mid X \rightarrow Y$
as an accepting automaton

\[
\begin{array}{c}

\text{Y=f(x)} \\
\downarrow \\
\text{a fact}
\end{array}
\]
1. This semantics is obtained by taking the product of the micro-step automata attached to each statement; the product is by synchronizing compatible facts
Micro-step semantics

1. This semantics is obtained by taking the product of the micro-step automata attached to each statement; the product is by synchronizing compatible facts

2. This is modular: we can compose micro-step automata attached to sub-systems
Micro-step semantics

1. This semantics is obtained by taking the product of the micro-step automata attached to each statement; the product is by synchronizing compatible facts.

2. This is modular: we can compose micro-step automata attached to sub-systems.

3. Such micro-step automata synchronize by exchanging facts, i.e., partial information regarding the status of the variables.
Micro-step semantics

1. This semantics is obtained by taking the product of the micro-step automata attached to each statement; the product is by synchronizing compatible facts.

2. This is modular: we can compose micro-step automata attached to sub-systems.

3. Such micro-step automata synchronize by exchanging facts, i.e., partial information regarding the status of the variables.

4. Since getting facts is monotonic, the exchange of facts can be performed in a distributed and chaotic way; it is confluent.
Micro-step semantics

1. This semantics is obtained by taking the product of the micro-step automata attached to each statement; the product is by synchronizing compatible facts.

2. This is modular: we can compose micro-step automata attached to sub-systems.

3. Such micro-step automata synchronize by exchanging facts, i.e., partial information regarding the status of the variables.

4. Since getting facts is monotonic, the exchange of facts can be performed in a distributed and chaotic way; it is confluent.

5. Warning: this does not solve desynchronized distribution since this still requires knowing the scope of the reaction.

• Constructive Semantics
• Separate compilation and a notion of interface
• Deploying over distributed (possibly asynchronous) architectures
• Use in architecture modeling and analysis
Interface theory for separate compilation

• Problem:
  - A synchronous program must be seen as a specification, as it has several possible implementations
  - Separate compilation consists in selecting one possible implementation in a modular way, with the intent of reusing the implementation in contexts that are not known in advance
  - As the Signal based example of the next slide will show, separate compilation must be handled with care

• Proposed approach:
  - Adopt the point of view of Interface Theories, where the Component and its Environment are seen as two players in a game
  - Define a refinement relation on such interfaces, from which rules for separate compilation will follow
The problem with separate compilation

This is a synchronous program (specification) instantaneous i/o dependencies are shown
The problem with separate compilation

This specification can be safely composed with another program as shown.
The problem with separate compilation

Here we show a compilation into sequential code that is compatible with the specification
The problem with separate compilation

Zero-delay circuit: Separate compilation can yield incompatible implementations
The problem with separate compilation

Separate compilation can yield incompatible implementations.

References for this graphical aspect of the problem:
[Raymond88]
[Maffeis-LeGuernic94]
[Aubry-LeGuernic96]
[Lublinerman-Tripakis08a,08b,09]
[Pouzet-Raymond09]

What about the general case of programs with multiple clocks?

Separate compilation can yield incompatible implementations.
The problem with separate compilation as in Signal

Example:

( U ^= V ^= X ^= Y
 | X ← U
 | Y ← V )
The problem with separate compilation as in Signal

Example:

```
( U ^= V ^= X ^= Y
 | X \leftarrow U
 | Y \leftarrow V )

| ( U ^= Y
 | U \leftarrow Y )
```

yields

```
( U ^= V ^= X ^= Y
 | X \leftarrow U \leftarrow Y \leftarrow V
 )
```

which is deadlock-free
The problem with separate compilation as in Signal

Example:

\[ ( U \leftarrow V \leftarrow X \leftarrow Y \leftarrow X \leftarrow Y \leftarrow U \leftarrow V ) \]

yields

\[ ( U \leftarrow V \leftarrow X \leftarrow Y \leftarrow X \leftarrow U \leftarrow Y \leftarrow V ) \]

which is deadlock-free

However, implementation

\[ ( U \leftarrow V \leftarrow X \leftarrow Y \leftarrow X, Y \leftarrow U, V ) \]
The problem with separate compilation as in Signal

Example:

\[
\begin{align*}
& ( U := V := X := Y \\
& \downarrow Y \leftarrow U \\
& \downarrow Y \leftarrow V ) \\
& \downarrow U := Y \\
& ( U := Y \\
& \downarrow U \leftarrow Y )
\end{align*}
\]

yields

\[
\begin{align*}
& ( U := V := X := Y \\
& \downarrow X \leftarrow U \leftarrow Y \leftarrow V \\
\end{align*}
\]

which is deadlock-free

However, implementation

\[
\begin{align*}
& ( U := V := X := Y \\
& \downarrow X, Y \leftarrow U, V ) \\
& \downarrow U := Y \\
& ( U := Y \\
& \downarrow U \leftarrow Y )
\end{align*}
\]

causes the deadlock

\[
\begin{align*}
& ( U := Y \\
& \downarrow U \leftrightarrow Y )
\end{align*}
\]
The problem with separate compilation as in Signal

Example:

\[
( \ U \ ^= \ V \ ^= \ X \ ^= \ Y \\
| \ X \ \leftarrow \ U \\
| \ Y \ \leftarrow \ V 
) \\
\]

\[
( \ U \ ^= \ Y \\
| \ U \ \leftarrow \ Y 
) \\
\]

yields

\[
( \ U \ ^= \ V \ ^= \ X \ ^= \ Y \\
| \ X \ \leftarrow \ U \ \leftarrow \ Y \ \leftarrow \ V 
) \\
\]

which is deadlock-free

However, implementation

\[
( \ U \ ^= \ V \ ^= \ X \ ^= \ Y \\
| \ X, Y \ \leftarrow \ U, V 
) \\
\]

\[
( \ U \ ^= \ Y \\
| \ U \ \leftarrow \ Y 
) \\
\]

causes the deadlock

\[
( \ U \ ^= \ Y \\
| \ U \ \leftrightarrow \ Y 
) \\
\]

References for this graphical aspect of the problem:

[Raymond88]
[Maffeis-LeGuernic94]
[Aubry-LeGuernic96]
[Lublinerman-Tripakis08a,08b,09]
[Pouzet-Raymond09]
The problem with separate compilation as in Signal

Example:

\[
( U \^= V \^= X \^= Y \^= Z \\
| X \leftarrow U \text{ when } Z>0 \\
| X \leftarrow V \text{ when } \neg Z>0 \\
| Z \leftarrow V \\
| Y \leftarrow V )
\]

If \( z \) is local, \( U,V,X,Y \) are visible, we can hide \( z \):

\[
( U \^= V \^= X \^= Y \\
| X \leftarrow U \\
| X \leftarrow V \\
| Y \leftarrow V )
\]

Every implementation of the original program is also a valid implementation of this more abstract interface.
Interface theory for separate compilation

• Problem:
  • A synchronous program must be seen as a specification, as it has several possible implementations
  • Separate compilation consists in selecting one possible implementation in a modular way, with the intent of reusing the implementation in contexts that are not known in advance

• Proposed approach:
  • Adopt the point of view of Interface Theories, where the Component and its Environment are seen as two players in a game
  • Define a refinement relation on such interfaces, from which rules for separate compilation will follow
Constraint in the Scott domain expressing that Y cannot be evaluated before X when predicate B evaluates to true.
$X \rightarrow_B Y$ : scheduling constraint

Micro-step automaton expressing that $Y$ cannot be evaluated before $X$ when predicate $B$ evaluates to true.

A fact: $B$ is absent or false
The essence of constructive semantics

Program

• Each program fragment generates a causality constraint inducing a scheduling constraint

Scheduling constraints

• Combine them with the actual evaluation of variables

• Each variable is evaluated once

• Take product of micro-step automata

Yields micro-step semantics for the program
The essence of constructive semantics

Y := f(X) ∥ H → X ∥ X →_H Y

as a micro-step automaton
Back to the scheduling constraint

\( X \rightarrow_B Y \)
A game theoretic approach for $X \rightarrow_B Y$

Suppose:
- Component has control over when to evaluate Y.
- Environment has control over when to evaluate B,X.
- No one has control over which value is assigned.

B = absent or false

B = true
A game theoretic approach: modalities

Component has control over when to evaluate Y
Environment has control over when to evaluate B,X
No one has control over which value is assigned
A game theoretic approach: using Marked Modal Interfaces

[Caillaud & Raclet] Marked Modal Interfaces
Transitions labeled *may / must*
Some states labeled *must*

- MMI yields an interface theory
- Refinement: removing *may* adding *must*
- Parallel composition supporting separate implementability
- Residuation
- Separate compil
  \[ \equiv \]
  Computing minimal implementations
Separate compilation followed by KPN execution

- Here we have used micro-step automata
- Why not using nets?
- Marked Modal Net Interfaces: MMNI
- Their implementations are safe nets...
- ... which execute as KPN
- Facts related to absence must be explicitly transmitted: additional signaling
- Could this simplify distribution?

- GALS (Globally Asynchronous Locally Synchronous)
- LTTA (Loosely Time Triggered Architectures)
Token based boolean dataflow à la Ed Lee (Kahnification)

\[ Y := X \text{ when } B \]
\[ | \quad X ^{=} B \]

The X-token passes or not depending on whether the boolean token is true (black) or false (red)

X and B have same clock
Token based boolean dataflow à la Ed Lee (Kahnification)

\[ Y := X \text{ when } B \]

\[ X \land B \]

\( X \) and \( B \) have same clock

The \( X \)-token passes or not depending on whether the boolean token is true (black) or false (red).
Token based boolean dataflow à la Ed Lee (Kahnification)

\[ Y := X \text{ when } B \]

| \text{X} \wedge B |

The \( X \)-token passes or not depending on whether the boolean token is true (black) or false (red).

That \( X \) and \( B \) possess identical clocks is part of the Signal specification.

Key difference: the pattern of input tokens is fixed (always a token on \( X \) and one on \( B \) for this actor, which makes it robust against asynchrony).
Token based boolean dataflow à la Ed Lee (Kahnification)

\[ Y := X \text{ when } B \]
\[ \mid X \ ^\wedge = B \]

Token based dataflow is isomorphic to synchronous software, i.e., \( \subseteq \) Signal MoCC

That \( X \) and \( B \) possess identical clocks is part of the Signal specification

Key difference: the pattern of input tokens is fixed (always a token on \( X \) and one on \( B \) for this actor, which makes it robust against asynchrony)

The \( X \)-token passes or not depending on whether the boolean token is true (black) or false (red)
The B-token is always consumed; a H-boolean token is created to indicate whether an X-token is consumed or not.

\[ Y := X \text{ when } B \]
\[ X \wedge B \]

\text{X and B}

\text{have clocks}

\text{subject to inclusion}
Token based boolean dataflow à la Ed Lee (Kahnification)

\[ Y := X \text{ when } B \]
\[ X \text{ } ^< \text{ } B \]

With additional signaling, Signal modules can be mapped to single buffer token based dataflow

The B-token is always consumed; a H-boolean token is created to indicate whether an X-token is consumed or not
Token based boolean dataflow à la Ed Lee (Kahnification)

\[ Y := X \text{ when } B \]
\[ | X \leftarrow B \]

With additional signaling, Signal modules can be mapped to single buffer token based dataflow.

The B-token is always consumed; a H-boolean token is created to indicate whether an X-token is consumed or not.

Translation can be structural, but this causes overhead in signaling ⇒ generate automatically minimal signaling.
Desynchronisation and mapping
Polychrony to GALS

- The above discussion provides hints for automatic correct-by-construction deployment over distributed GALS architectures

- Can also be seen as a way to reduce the number of handshakes in asynchronous hardware

- A large body of results has been developed by [Caillaud & Girault 1996]
  [Caillaud, Benveniste, LeGuernic 2000]
  [Caillaud, Potop Butucaru 2005, Potop Butucaru & al 2008] to algebraically characterize those synchronous programs equivalent to token based data flow nets

- Synthesis methods follow accordingly
Comparison with other Models of Computation and Communication and Related

- Synchronous paradigms
- Kahn networks, token based Boolean dataflow nets (Ed Lee)
- GALS (Globally Asynchronous Locally Synchronous)
- LTTA (Loosely Time Triggered Architectures)
Desynchronisation and mapping
Polychrony to GALS: the issues (0)
Desynchronisation and mapping
Polychrony to GALS: the issues (0)
Desynchronisation and mapping
Polychrony to GALS: the issues (0)
Desynchronisation and mapping
Polychrony to GALS: the issues (1)

• Local to a synchronous component communicating asynchronously with its environment:
  • reconstruct the successive synchronous reactions without external triggers

• To preserve functional semantics of communication, from synch to asynch:
  • The set of synch runs should be robust against desynchronisation
  • Interblocking properties should not be relaxed by desynchronisation

• Solution: [Potop Caillaud 2005, Potop 2008]
Desynchronisation and mapping Polychrony to GALS: the issues (2)

- Local to a synchronous component communicating asynchronously with its environment:

- Being able to reconstruct the successive synchronous reactions without external triggers: **endochrony** (no decision based on absence)

\[
Y := X \text{ when } B \\
| X < B
\]

\[
Y := X \text{ when } B \\
| X = \text{ when } H \\
| H = B
\]
To preserve functional semantics of communication, from synch to asynch:

- The set of synch runs should be robust against desynchronisation: **weak endochrony**
  
  \[ P \text{ endochronous} \Rightarrow P \text{ weakly endochronous} \]

- \(P_1, P_2\) **weakly endochronous** \(\Rightarrow\) \(P_1 \mid P_2\) **weakly endochronous**

- \(P_1, P_2\) **endochronous** \(\Rightarrow\) \(P_1 \mid P_2\) **endochronous**
To preserve functional semantics of communication, from synch to asynch:

- Interblocking properties should not be relaxed by desynchronisation (otherwise desynchronisation may remove deadlocks): **weak isochrony**

- Sufficient condition: synchronous composition does not deadlock
Desynchronisation and mapping Polychrony to GALS: the issues (4)

To preserve functional semantics of communication, from synch to asynch:

- Interblocking properties should not be relaxed by desynchronisation (otherwise desynchronisation may remove deadlocks): weak isochrony

- Sufficient condition: synchronous composition does not deadlock

A comprehensive set of results has been obtained by [Caillaud and Potop 05, Potop 2008]; earlier results by Benveniste, Caillaud and le Guernic; also methods and tools by Girault
Comparison with other Models of Computation and Communication and Related

Enriching Signal models with nonfunctional characteristics

\[
(\begin{array}{l}
(B := (ZX \leq 0)) \\
| IN ^= \text{when } B = [B] \\
| H ^= B ^= X ^= ZX)
\end{array})
\]

\[
(\begin{array}{l}
X \leftrightarrow IN \text{ when } B \\
X \leftrightarrow ZX \text{ when not } B \\
B \leftrightarrow (H,ZX) \\
[B] \leftrightarrow B \\
ZX \leftrightarrow H \\
IN \leftrightarrow [B]
\end{array})
\]

Synchro + scheduling
(recall)
Enriching Signal models with nonfunctional characteristics

( ( B := (ZX ≤ 0) | IN ^= when B = [B] | H ^= B ^= X ^= ZX ) |
| X ← IN when B |
| X ← ZX when not B |
| B ← (H,ZX) |
| [B] ← B |
| ZX ← H |
| IN ← [B] ) )

Synchro + scheduling
Focus on the two selected statements
Enriching Signal models with nonfunctional characteristics

(  
  (  
    B := (ZX ≤ 0)  
    | IN ^= when B = [B]  
    | H ^= B ^= X ^= ZX  
  )  
  | X ← IN when B  
  | δx = (δIN +δ’) when B  
  | X ← ZX when not B  
  | B ← (H,ZX)  
  | δB = max(δH,δZX)  
  | [B] ← B  
  | ZX ← H  
  | IN ← [B]  
)

Enriched with timing evaluation; can be generated automatically, for all statements
Architecture modeling and analysis (RT-Builder)

**Conclusion**

Signal Polychronous MoCC

- Clear and solid semantics ⇒
  - reproducible simulations
- \{synchro+scheduling\} calculus ⇒
  - Code generation
  - Interface models
  - Abstract/refine
- Cross-viewpoint models
- Relates and adjusts to other MoCCs ⇒
  - Architecture study

**Tools**

- **RT-Builder** by Geensys
  (formerly TNI Software)
- **Polychrony**
  experimental and academic freeware by INRIA
