challenges

Natural images follow a probability distribution, denoted by

$$x \sim q(x)$$

Forward diffusion process consists in adding noise to original data, gradually switching from q to a normal distribution:

$$\mathbf{x}_0 \sim q(x) \tag{1}$$

$$\mathbf{x}_t | \mathbf{x}_{t-1} \sim q(\mathbf{x}_t | \mathbf{x}_{t-1}) = \mathcal{N}(\sqrt{1 - \beta_t} \mathbf{x}_{t-1}, \beta_t \mathbf{I}) \tag{2}$$

$$\mathbf{x}_t | \mathbf{x}_0 \sim \mathcal{N}(\sqrt{\alpha_t} \mathbf{x}_0; \sqrt{1 - \alpha_t} \mathbf{I}) \tag{3}$$

With α_t going from 0 at 1 when t goes from T at 0. We thus obtain $\mathbf{x}_T \sim \mathcal{N}(0, \mathbf{I})$.

Graph reduction: Sampling

Graph reduction: Coarsening

Topology change

On-the-sphere learning

Image processing for Ecological challenges

Using the diffusion model ϵ_θ , we can predict \mathbf{x}_{t-1} :

$$\mathbf{x}_{t-1} = \sqrt{\alpha_{t-1}} \frac{\mathbf{x}_t - \sqrt{1 - \alpha_t} \epsilon_\theta(\mathbf{x}_t, t)}{\sqrt{\alpha_t}} + \sqrt{1 - \alpha_{t-1}} \epsilon_\theta(\mathbf{x}_t, t) \quad (4)$$

We can estimate the current image at the step t that we note $x_{0|t}$ with:

$$\mathbf{x}_{0|t}(\epsilon_\theta(\mathbf{x}_t, t)) = \frac{\mathbf{x}_t - \sqrt{1 - \alpha_t} \epsilon_\theta(\mathbf{x}_t, t)}{\sqrt{\alpha_t}} \quad (5)$$

and thus we can rewrite:

$$\mathbf{x}_{t-1} = \sqrt{\alpha_{t-1}} x_{0|t}(\epsilon_\theta(\mathbf{x}_t, t)) + \sqrt{1 - \alpha_{t-1}} \epsilon_\theta(\mathbf{x}_t, t) \quad (6)$$

\mathbf{x}_{t-1} becomes a combination between, the estimated sample $x_{0|t}$ and what is commonly called the direction pointing to x_t

Image processing for Ecological challenges

Michael M. Bronstein, Joan Bruno, Yann LeCun, Arthur Szlam, and Pierre Vandergheynst

Many scientific fields study data with an underlying structure that is non-Euclidean. Some examples include social networks in computational social sciences, sensor networks in communications, functional networks in brain imaging, regulatory networks in genetics, and meshed surfaces in computer graphics. In many applications, such geometric data are large and complex (in the case of social networks, on the scale of billions) and are natural targets for machine-learning techniques. In particular, we would like to use deep neural networks, which have recently proven to be powerful tools for a broad range of problems from computer vision, natural-language processing, and audio analysis. However, these tools have been most successful on data with an underlying Euclidean or grid-like structure and in cases where the intricacies of these structures are built into networks used to model them.

Geometric deep learning is an umbrella term for emerging techniques attempting to generalize (structured) deep neural models to non-Euclidean domains, such as graphs and manifolds. The purpose of this article is to overview different examples of geometric deep-learning problems and present available solutions, key difficulties, applications, and future research directions in this nascent field.

Overview of deep learning

Deep learning refers to learning complicated concepts by building them from simpler ones in a hierarchical or multilayer manner. Artificial neural networks are popular realizations of such deep multilayer hierarchies. In the past few years, the growing computational power of modern graphics processing unit (GPU)-based computers and the availability of large training data sets have allowed successfully training neural networks with many layers and degrees of freedom (DoF) [1]. This has led to qualitative breakthroughs on a wide variety of tasks, from speech recognition [2], [3] and machine translation [4] to image analysis and computer vision [5]–[11] (see [12]

Let us consider a signal \mathbf{f} defined on a graph \mathcal{G} that is bandlimited with a bandwidth λ_{\max} :

$$\forall \lambda_l > \lambda_{\max}, \hat{f}(\lambda_l) = 0$$

The set of bandlimited signals λ_{\max} with bandwidth is called the **Paley-Wiener space** $PW_{\lambda_{\max}}(\mathcal{G})$.

A **uniqueness set** for $PW_{\lambda_{\max}}(\mathcal{G})$ is a subset of vertices $\mathcal{S} \subset \mathcal{V}$ for which

$$\forall f, g \in PW_{\lambda_{\max}}(\mathcal{G}), f(\mathcal{S}) = g(\mathcal{S}) \Rightarrow f = g$$

The smallest **uniqueness set** for $PW_{\lambda_l}(\mathcal{G})$ has a size of l

On-the-sphere learning

Image processing for Ecological challenges

Let $f \in PW_{\lambda_n}$, and \mathcal{S} be a minimum uniqueness set.
Estimate the graph Fourier coefficients

$$\mathbf{f} = \begin{bmatrix} \mathbf{f}(\mathcal{S}) \\ \mathbf{f}(\mathcal{S}^c) \end{bmatrix} = \begin{bmatrix} \mathbf{u}_1(\mathcal{S}) & \dots & \mathbf{u}_N(\mathcal{S}) \\ \mathbf{u}_1(\mathcal{S}^c) & \dots & \mathbf{u}_N(\mathcal{S}^c) \end{bmatrix} \begin{bmatrix} \hat{\mathbf{f}}(1) \\ \vdots \\ \hat{\mathbf{f}}(n) \\ \mathbf{0} \end{bmatrix}$$

Thus

$$\begin{bmatrix} \hat{\mathbf{f}}(1) \\ \vdots \\ \hat{\mathbf{f}}(n) \end{bmatrix} = (\tilde{\mathbf{U}}_n(\mathcal{S}))^{-1} \mathbf{f}(\mathcal{S})$$

with $\tilde{\mathbf{U}}_n$ being the n first eigenvectors.

Finally,

$$\mathbf{f}(\mathcal{S}^c) = \tilde{\mathbf{U}}_n(\mathcal{S}^c) \begin{bmatrix} \hat{\mathbf{f}}(1) \\ \vdots \\ \hat{\mathbf{f}}(n) \end{bmatrix}$$

On-the-sphere learning

Image processing for Ecological challenges

In the equation $\begin{bmatrix} \hat{\mathbf{f}}(1) \\ \vdots \\ \hat{\mathbf{f}}(n) \end{bmatrix} = (\tilde{\mathbf{U}}_n(\mathcal{S}))^{-1} \mathbf{f}(\mathcal{S})$, the matrix $\tilde{\mathbf{U}}_n(\mathcal{S})$

should be invertible.

Sampling algorithms consist in finding the set \mathcal{S} for which, $\tilde{\mathbf{U}}_n(\mathcal{S})$ is invertible

Initialize: $\mathcal{S} \leftarrow \mathcal{V}_i$ where i is the index of any nonzero element of first eigenvector

for $m = 2 \rightarrow n$ **do**

 Compute $\mathbf{x} = \text{null}(\tilde{\mathbf{U}}_m(\mathcal{S}))$

 Compute $\mathbf{b} = \tilde{\mathbf{U}}_m(\mathcal{S}^c) \mathbf{x}$

$i \leftarrow \text{argmax}_i (|\mathbf{b}(i)|)$

$\mathcal{S} \leftarrow \mathcal{S} \cup \mathcal{S}_c(i)$

end

[D. E. Tzamarias, P. Akyazi, and P. Frossard, "A novel method for sampling bandlimited graph signals," in Proceedings of EUSIPCO, no. CONF, 2018.]

Coarsening: From an initial graph $\mathcal{G} = \{\mathcal{V}, \mathcal{E}, \mathbf{L}\}$ with N nodes and a signal \mathbf{x} , build a new coarsened graph \mathcal{G}_c with N_c nodes:

$$\mathbf{x}_c = \mathbf{P}\mathbf{x}$$

$$\tilde{\mathbf{x}} = \mathbf{P}^+ \mathbf{x}_c$$

where $\mathbf{P} \in \mathbb{R}^{N_c \times N}$ are matrices with more columns than rows and \mathbf{P}^+ the pseudo-inverse.

$$\mathbf{L}_c = \mathbf{P}^\top \cdot \mathbf{L} \cdot \mathbf{P}^+ \qquad \mathbf{L} \approx \mathbf{P}^\top \cdot \mathbf{L}_c \cdot \mathbf{P}$$

With the constraint that \mathbf{L}_c is a graph Laplacian, we have:

$$\mathbf{P}(r, i) = \begin{cases} \frac{1}{\|\mathcal{V}^{(r)}\|} & \text{if } v_i \in \mathcal{V}^{(r)} \\ 0 & \text{otherwise} \end{cases} \quad (8)$$

$$\mathbf{P}^+(i, r) = \begin{cases} 1 & \text{if } v_i \in \mathcal{V}^{(r)} \\ 0 & \text{otherwise} \end{cases} \quad (9)$$

Let α be the convolution kernel. The *DeepSphere* convolution is:

$$\mathbf{x} \star \alpha := \sum_{l=0}^L \alpha_l \mathbf{L}^l \mathbf{x},$$

where L is the polynomial degree. It controls the kernel widows size.
→ Only one weight per neighborhood (isotropic filter).

Example of 1-hop:

$$(\mathbf{x} \star \alpha)(i) := \alpha_0 x_i + \alpha_1 \cdot \left(\sum_{k=1}^8 l_{i, \mathcal{N}_i(k)} x_{\mathcal{N}_i(k)} \right)$$

where $\mathcal{N}_i(k)$ is the k^{th} neighbor of pixel i .

Answer the following questions

- What is the societal challenge that is tackled ?
- What is the scientific problem that is tackled ?
- What is the contribution ?
- What is the obtained result ?

Societal challenges:

- Climate change measurement and modeling
- Energy Consumption reduction (automation, optimization)
- ...

Scientific challenges:

- Image super-resolution
- Image/Video compression
- Image understanding
- Data modeling
- ...

Image processing for Ecological challenges

Katy Freeway, Houston (Wikipedia)

Jevon's paradox (or rebound effect):

As technological improvements increase the efficiency with which a resource is employed, the total consumption of that resource may increase rather than decrease. (Wikipedia)

- Direct vs indirect
- comes when the usage of the technology is not questioned
- limited by sensitization and by thinking the problem globally

Some awareness: maintain *conviviality*

In *Tools for Conviviality* (Ivan Illich 1973):

Recent development brings:

- modernized poverty
- dependency
- out-of-control system

Instead we should "*invert the present deep structure of tools*" in order to "*give people tools that guarantee their right to work with independent efficiency*" → technology for emancipation

THE CRITERIA FOR ANY LOW-TECH INNOVATION APPROACH:

STRONG SUSTAINABILITY

1 Sobriety

Relies on the essentials and tends toward the technological optimum: lowest technological intensity and greatest simplicity ensuring needs be met with a high level of reliability.

2 Efficiency

Minimizes the consumption of energy and resources, from extraction of raw materials through production, distribution and use to end of life.

3 Durability

Presents maximum technical, functional, ecological as well as human viability in the short, medium and long term.

COLLECTIVE RESILIENCE

4 Maintainability

Can be maintained and repaired by users themselves so far as possible, using standard parts and materials.

5 Accessibility

Offers maximum ease of use.

6 Autonomization

Is made from resources that are exploited and transformed as locally as possible.

CULTURAL TRANSFORMATION

7 Empowerment

Facilitates appropriation by the greatest number, gives power to citizens and communities.

8 Connectedness

Promotes the sharing of knowledge and know-how, cooperation, solidarity, social cohesion and links between communities.

9 Simplification

Decomplexifies society at the socio-economic and organizational levels based on reflection about needs and vulnerabilities.
